## System's computations

- The behaviors (computations) of a system can be seen as sequences of propositions.

```
MODULE main
VAR done: Boolean;
ASSIGN
  init(done) := 0;
  next(done) := case
    !done: {0,1};
    done: done;
  esac;
```

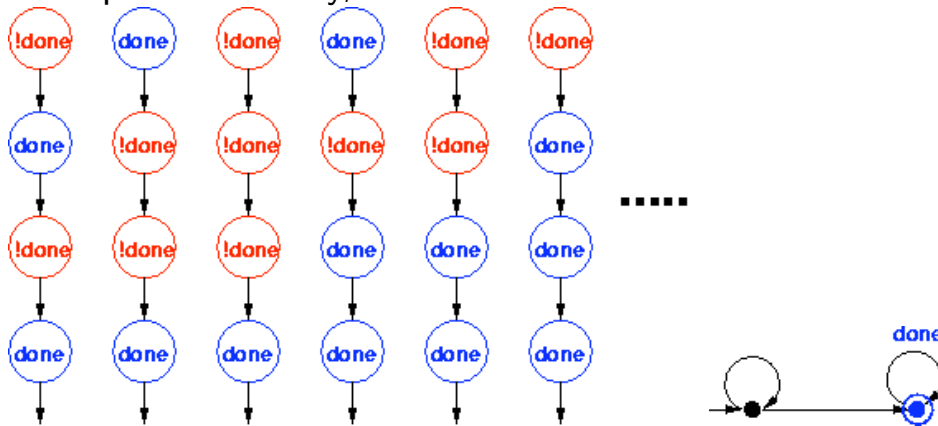

- Since the state space is finite, the set of computations can be represented by a finite automaton.

# Correct computations

- Some computations are correct and others are not acceptable.
- We can build an automaton for the set of all acceptable computations.
- Example: eventually, done will be true forever.

# Language Containment Problem

- Solution to the verification problem  
⇒ Check if language of the system automaton is contained in the language accepted by the property automaton.
- The language containment problem is the problem of deciding if a language is a subset of another language.

$$\mathcal{L}(A_1) \subseteq \mathcal{L}(A_2) \iff \mathcal{L}(A_1) \cap \overline{\mathcal{L}(A_2)} = \{\}$$

To solve the language containment problem, we need to know:

- 1 how to complement an automaton,
- 2 how to intersect two automata,
- 3 how to check the language emptiness of an automaton.

# Finite Word Languages

- An **Alphabet**  $\Sigma$  is a collection of symbols (letters).  
E.g.  $\Sigma = \{a, b\}$ .
- A **finite word** is a finite sequence of letters. (E.g. *aabb*.)  
The set of all **finite** words is denoted by  $\Sigma^*$ .
- A **language**  $U$  is a set of words, i.e.  $U \subseteq \Sigma^*$ .

**Example:** Words over  $\Sigma = \{a, b\}$  with equal number of *a*'s and *b*'s.  
(E.g. *aabb* or *abba*.)

**Language recognition problem:**  
determine whether a word belongs to a language.

**Automata** are computational devices able to solve language recognition problems.

# Finite State Automata

Basic model of computational systems with finite memory.

## Widely applicable

- Embedded System Controllers.  
Languages: Ester-el, Lustre, Verilog.
- Synchronous Circuits.
- Regular Expression Pattern Matching  
Grep, Lex, Emacs.
- Protocols  
Network Protocols  
Architecture: Bus, Cache Coherence, Telephony,...

## Notation

$a, b \in \Sigma$  finite alphabet.

$u, v, w \in \Sigma^*$  finite words.

$\epsilon$  empty word.

$u.v$  catenation.

$u^i = u.u \dots u$  repeated  $i$ -times.

$U, V \subseteq \Sigma^*$  Finite word languages.

# FSA Definition

## Nondeterministic Finite State Automaton (NFA):

NFA is  $(Q, \Sigma, \delta, I, F)$

$Q$  Finite set of states.

$\Sigma$  is a finite alphabet

$I \subseteq Q$  set of initial states.

$F \subseteq Q$  set of final states.

$\delta \subseteq Q \times \Sigma \times Q$  transition relation (edges).

We use  $q \xrightarrow{a} q'$  to denote  $(q, a, q') \in \delta$ .

## Deterministic Finite State Automaton (DFA):

DFA has  $\delta : Q \times \Sigma \rightarrow Q$ , a **total function**.

Single initial state  $I = \{q_0\}$ .

# Regular Languages

- A **run** of NFA  $A$  on  $u = a_0, a_1, \dots, a_{n-1}$  is a finite sequence of states  $q_0, q_1, \dots, q_n$  s.t.  $q_0 \in I$  and  $q_i \xrightarrow{a_i} q_{i+1}$  for  $0 \leq i < n$ .
- An **accepting run** is one where the last state  $q_n \in F$ .
- The language accepted by  $A$   
 $\mathcal{L}(A) = \{u \in \Sigma^* \mid A \text{ has an accepting run on } u\}$
- The languages accepted by a NFA are called **regular languages**.

# Finite State Automata

Example: DFA  $A_1$  over  $\Sigma = \{a, b\}$ .

Recognizes words which do not end in  $b$ .

NFA  $A_2$ . Recognizes words which end in  $b$ .

## Determinisation

**Theorem (determinisation)** Given a NFA  $A$  we can construct a DFA  $A'$  s.t.  $\mathcal{L}(A) = \mathcal{L}(A')$ . Size  $|A'| = 2^{O(|A|)}$ .

- Each state of  $A'$  corresponds to a set  $\{s_1, \dots, s_j\}$  of states in  $A$  ( $Q' \subseteq 2^Q$ ), with the intended meaning that :
  - $A'$  is in the state  $\{s_1, \dots, s_j\}$  if  $A$  is in one of the states  $s_1, \dots, s_j$
- The deterministic transition relation  $\delta' : 2^Q \times \Sigma \mapsto 2^Q$  is
  - $\{s\} \xrightarrow{a} \{s_i \mid s \xrightarrow{a} s_i\}$
  - $\{s_1, \dots, s_j, \dots, s_n\} \xrightarrow{a} \bigcup_{j=1}^n \{s_i \mid s_j \xrightarrow{a} s_i\}$
- The (unique) initial state is  $I' =_{\text{def}} \{s_i \mid s_i \in I\}$
- The set of final states  $F'$  is such that  $\{s_1, \dots, s_n\} \in F'$  iff  $s_i \in F$  for some  $i \in \{1, \dots, n\}$

## Determinisation [cont.]

NFA  $A_2$ : Words which end in  $b$ .

$A_2$  can be determinised into the automaton  $DA_2$  below.

States =  $2^Q$ .

There are NFAs of size  $n$  for which the size of the minimum sized DFA must have size  $O(2^n)$ .

## Closure Properties

**Theorem (Boolean closure)** Given NFA  $A_1, A_2$  over  $\Sigma$  we can construct NFA  $A$  over  $\Sigma$  s.t.

- $\mathcal{L}(A) = \overline{\mathcal{L}(A_1)}$  (Complement).  $|A| = 2^{O(|A_1|)}$ .
- $\mathcal{L}(A) = \mathcal{L}(A_1) \cup \mathcal{L}(A_2)$  (union).  $|A| = |A_1| + |A_2|$ .
- $\mathcal{L}(A) = \mathcal{L}(A_1) \cap \mathcal{L}(A_2)$  (intersection).  $|A| = |A_1| \cdot |A_2|$ .

# Complementation of a NFA

A NFA  $A = (Q, \Sigma, \delta, I, F)$  is complemented by:

- determinizing it into a DFA  $A' = (Q', \Sigma', \delta', I', F')$
- complementing it:  $\overline{A'} = (Q', \Sigma', \delta', I', \overline{F'})$
- $|\overline{A'}| = |A'| = 2^{O(|A|)}$

# Union of two NFAs

Two NFAs  $A_1 = (Q_1, \Sigma_1, \delta_1, I_1, F_1)$ ,  $A_2 = (Q_2, \Sigma_2, \delta_2, I_2, F_2)$ ,  
 $A = A_1 \cup A_2 = (Q, \Sigma, \delta, I, F)$  is defined as follows

- $Q := Q_1 \cup Q_2$ ,  $I := I_1 \cup I_2$ ,  $F := F_1 \cup F_2$
- $R(s, s') := \begin{cases} R_1(s, s') & \text{if } s \in Q_1 \\ R_2(s, s') & \text{if } s \in Q_2 \end{cases}$

$\implies A$  is an automaton which just runs nondeterministically either  $A_1$  or  $A_2$

- $\mathcal{L}(A) = \mathcal{L}(A_1) \cup \mathcal{L}(A_2)$
- $|A| = |A_1| + |A_2|$

# Synchronous Product Construction

Let  $A_1 = (Q_1, \Sigma, \delta_1, l_1, F_1)$  and  $A_2 = (Q_2, \Sigma, \delta_2, l_2, F_2)$ . Then,  $A_1 \times A_2 = (Q, \Sigma, \delta, l, F)$  where

- $Q = Q_1 \times Q_2$ .       $l = l_1 \times l_2$ .
- $F = F_1 \times F_2$ .
- $\langle p, q \rangle \xrightarrow{a} \langle p', q' \rangle$  iff  $p \xrightarrow{a} p'$  and  $q \xrightarrow{a} q'$ .

**Theorem**  $\mathcal{L}(A_1 \times A_2) = \mathcal{L}(A_1) \cap \mathcal{L}(A_2)$ .

## Example

- $A_1$  recognizes words with an even number of  $b$ 's.
- $A_2$  recognizes words with a number of  $a$ 's multiple of 3.
- The Product Automaton  $A_1 \times A_2$  with  $F = \{s_0, t_0\}$ .

# Regular Expressions

Syntax:  $\emptyset$  |  $\epsilon$  |  $a$  |  $reg_1.reg_2$  |  $reg_1|reg_2$  |  $reg^*$ .

Every regular expression  $reg$  denotes a language  $\mathcal{L}(reg)$ .

**Example:**  $a^*. (b|bb). a^*$ . The words with either 1  $b$  or 2 consecutive  $b$ 's.

**Theorem:** For every regular expression  $reg$  we can construct a language equivalent NFA of size  $O(|reg|)$ .

**Theorem:** For every DFA  $A$  we can construct a language equivalent regular expression  $reg(A)$ .

# Infinite Word Languages

Modeling infinite computations of reactive systems.

- An  $\omega$ -word  $\alpha$  over  $\Sigma$  is an **infinite** sequence

$$a_0, a_1, a_2 \dots$$

Formally,  $\alpha : \mathbb{N} \rightarrow \Sigma$ .

The set of all infinite words is denoted by  $\Sigma^\omega$ .

- A  $\omega$ -language  $L$  is collection of  $\omega$ -words, i.e.  $L \subseteq \Sigma^\omega$ .

**Example** All words over  $\{a, b\}$  with infinitely many  $a$ 's.

## Notation

**omega words**  $\alpha, \beta, \gamma \in \Sigma^\omega$ .

**omega-languages**  $L, L_1 \subseteq \Sigma^\omega$

For  $u \in \Sigma^+$ , let  $u^\omega = u.u.u \dots$

# Omega-Automata

We consider automaton running over infinite words.

Let  $\alpha = aabbbb \dots$ . There are several possible runs.

Run  $\rho_1 = s_1, s_1, s_1, s_1, s_2, s_2 \dots$

Run  $\rho_2 = s_1, s_1, s_1, s_1, s_1, s_1 \dots$

**Acceptance Conditions** Büchi, (Muller, Rabin, Street).

Acceptance is based on states occurring infinitely often

**Notation** Let  $\rho \in Q^\omega$ . Then,

$$\text{Inf}(\rho) = \{s \in Q \mid \exists^\infty i \in \mathbb{N}. \rho(i) = s\}.$$

(The set of states occurring infinitely many times in  $\rho$ .)

# Büchi Automata

## Nondeterministic Büchi Automaton

$A = (Q, \Sigma, \delta, I, F)$ , where  $F \subseteq Q$  is the set of accepting states.

- A run  $\rho$  of  $A$  on omega word  $\alpha$  is an infinite sequence  $\rho = q_0, q_1, q_2, \dots$  s.t.  $q_0 \in I$  and  $q_i \xrightarrow{a_i} q_{i+1}$  for  $0 \leq i$ .
- The run  $\rho$  is **accepting** if  $\text{Inf}(\rho) \cap F \neq \emptyset$ .
- The language accepted by  $A$   
 $\mathcal{L}(A) = \{\alpha \in \Sigma^\omega \mid A \text{ has an accepting run on } \alpha\}$

## Büchi Automaton: Example

Let  $\Sigma = \{a, b\}$ .

Let a Deterministic Büchi Automaton (DBA)  $A_1$  be

- With  $F = \{s_1\}$  the automaton recognizes words with infinitely many  $a$ 's.
- With  $F = \{s_2\}$  the automaton recognizes words with infinitely many  $b$ 's.

## Büchi Automaton: Example (2)

Let a Nondeterministic Büchi Automaton (NBA)  $A_2$  be

With  $F = \{s_2\}$ , automaton  $A_2$  recognizes words with finitely many  $a$ . Thus,  $\mathcal{L}(A_2) = \overline{\mathcal{L}(A_1)}$ .

## Deterministic vs. Nondeterministic Büchi Automata

**Theorem** *DBAs are strictly less powerful than NBAs.*

The subset construction does not work: let  $DA_2$  be

- $DA_2$  is not equivalent to  $A_2$  (e.g., it recognizes  $(b.a)^\omega$ )
- There is no DBA equivalent to  $A_2$

# Closure Properties

## Theorem (union, intersection)

For the NBAs  $A_1, A_2$  we can construct

- the NBA  $A$  s.t.  $\mathcal{L}(A) = \mathcal{L}(A_1) \cup \mathcal{L}(A_2)$ .  $|A| = |A_1| + |A_2|$
- the NBA  $A$  s.t.  $\mathcal{L}(A) = \mathcal{L}(A_1) \cap \mathcal{L}(A_2)$ .  $|A| = |A_1| \cdot |A_2| \cdot 2$ .

## Union of two NBAs

Two NBAs  $A_1 = (Q_1, \Sigma_1, \delta_1, I_1, F_1)$ ,  $A_2 = (Q_2, \Sigma_2, \delta_2, I_2, F_2)$ ,  
 $A = A_1 \cup A_2 = (Q, \Sigma, \delta, I, F)$  is defined as follows

- $Q := Q_1 \cup Q_2$ ,  $I := I_1 \cup I_2$ ,  $F := F_1 \cup F_2$
- $R(s, s') := \begin{cases} R_1(s, s') & \text{if } s \in Q_1 \\ R_2(s, s') & \text{if } s \in Q_2 \end{cases}$

$\implies A$  is an automaton which just runs nondeterministically either  $A_1$  or  $A_2$

- $\mathcal{L}(A) = \mathcal{L}(A_1) \cup \mathcal{L}(A_2)$
- $|A| = |A_1| + |A_2|$
- (same construction as with ordinary automata)

# Synchronous Product of NBAs

Let  $A_1 = (Q_1, \Sigma, \delta_1, l_1, F_1)$  and  $A_2 = (Q_2, \Sigma, \delta_2, l_2, F_2)$ .

Then,  $A_1 \times A_2 = (Q, \Sigma, \delta, l, F)$ , where

$$Q = Q_1 \times Q_2 \times \{1, 2\}.$$

$$l = l_1 \times l_2 \times \{1\}.$$

$$F = F_1 \times Q_2 \times \{1\}.$$

$\langle p, q, 1 \rangle \xrightarrow{a} \langle p', q', 1 \rangle$  iff  $p \xrightarrow{a} p'$  and  $q \xrightarrow{a} q'$  and  $p \notin F_1$ .

$\langle p, q, 1 \rangle \xrightarrow{a} \langle p', q', 2 \rangle$  iff  $p \xrightarrow{a} p'$  and  $q \xrightarrow{a} q'$  and  $p \in F_1$ .

$\langle p, q, 2 \rangle \xrightarrow{a} \langle p', q', 2 \rangle$  iff  $p \xrightarrow{a} p'$  and  $q \xrightarrow{a} q'$  and  $q \notin F_2$ .

$\langle p, q, 2 \rangle \xrightarrow{a} \langle p', q', 1 \rangle$  iff  $p \xrightarrow{a} p'$  and  $q \xrightarrow{a} q'$  and  $q \in F_2$ .

**Theorem**  $\mathcal{L}(A_1 \times A_2) = \mathcal{L}(A_1) \cap \mathcal{L}(A_2)$ .

## Product of NBAs: Intuition

- The automaton remembers two tracks, one for each source NBA, and it points to one of the two tracks
- As soon as it goes through an accepting state of the current track, it switches to the other track  
 $\implies$  to visit infinitely often a state in  $F$  (i.e.,  $F_1$ ), it must visit infinitely often some state also in  $F_2$
- Important subcase: If  $F_2 = Q_2$ , then
$$Q = Q_1 \times Q_2.$$
$$l = l_1 \times l_2.$$
$$F = F_1 \times Q_2.$$

# Product of NBAs: Example

# Closure Properties (2)

## Theorem (complementation)

For the NBA  $A_1$  we can construct an NBA  $A_2$  such that  $\mathcal{L}(A_2) = \overline{\mathcal{L}(A_1)}$ .  
 $|A_2| = O(2^{|A_1|} \cdot \log(|A_1|))$ .

## Method: (hint)

- (1) convert a Büchi automaton into a Non-Deterministic Rabin automaton.
- (2) determinize and Complement the Rabin automaton
- (3) convert the Rabin automaton into a Büchi automaton

# Omega Regular Expressions

A language is called  $\omega$ -regular if it has the form  $\cup_{i=1}^n U_i \cdot (V_i)^\omega$  where  $U_i, V_i$  are regular languages.

**Theorem** A language  $L$  is  $\omega$ -regular iff it is NBA-recognizable.

- On-the-fly construction of Büchi Automata
- Complexity

## Nonemptiness of NFA Automata

- The **nonemptiness** problem for an automaton is to decide whether there is at least one word for which there is an accepting run.
- For NFA (i.e., standard nondeterministic finite automata), nonemptiness algorithms are based on **reachability**
- In Datalog/Prolog notation:

```
nonempty :- initial(X), cn(X, Y), final(Y) .
```

```
cn(X, Y) :- r(X, A, Y) .  
cn(X, Y) :- r(X, A, Z), cn(Z, Y) .
```

where  $\text{initial}(X)$  denotes that  $X$  is an initial state;  $\text{final}(X)$  denotes that  $X$  is a final state;  $r(X, A, Y)$  denotes that a transition from  $X$  to  $Y$  reading  $A$ ; and  $\text{cn}(\cdot, \cdot)$  is **the transitive closure** of  $r(X, A, Y)$  projected on  $X, Y$ .

Notice that  $\text{cn}(\cdot, \cdot)$  is not expressible in FOL.

- Reachability is a well-known problem on graphs, its complexity is NLOGSPACE-complete. →

**Thm.** *Nonemptiness for NFA  $a$  is NLOGSPACE-complete.*

Practical algorithms have a **linear** cost.

## Nonemptiness of Büchi Automata

- For Büchi automata, nonemptiness algorithms are based on **fair reachability**
- In Datalog/Prolog notation:

```
nonempty :- initial(X), cn(X, Y), final(Y), cn(Y, Y) .
```

```
cn(X, Y) :- r(X, A, Y) .  
cn(X, Y) :- r(X, A, Z), cn(Z, Y) .
```

where, as before,  $\text{initial}(X)$  denotes that  $X$  is an initial state;  $\text{final}(X)$  denotes that  $X$  is a final state;  $r(X, A, Y)$  denotes that a transition from  $X$  to  $Y$  reading  $A$ ; and  $\text{cn}(\cdot, \cdot)$  is **the transitive closure** of  $r(X, A, Y)$  projected on  $X, Y$ .

- Fair reachability amounts to two separate reachability problems: (1) reach a final state from the initial state, (2) from that final state reach itself through a loop.
- Fair reachability has the same complexity as reachability: NLOGSPACE-complete. →

**Thm.** *Nonemptiness for Büchi automata is NLOGSPACE-complete.*

Practical algorithms have a **linear** cost.

## NFA emptiness checking

- Equivalent of finding a final state reachable from an initial state.
- It can be solved with a DFS or a BFS.
- A DFS finds a counterexample on the fly (it is stored in the stack of the procedure).
- A BFS finds a final state reachable with a shortest counterexample, but it requires a further backward search to reproduce the path.
- Complexity:  $O(n)$ .
  
- Henceafter, assume w.l.o.g. that there is only one initial state.

## NBA emptiness checking

- Equivalent of finding an accepting cycle reachable from an initial state.
- A naive algorithm:
  - a DFS finds the final states  $f$  reachable from an initial state;
  - for each  $f$ , a DFS finds if there exists a loop.
  - Complexity:  $O(n^2)$ .
- SCC-based algorithm:
  - the Tarjan's algorithm uses a DFS to finds the SCCs of a graph in linear time;
  - another DFS finds if a non-trivial final SCC is reachable from an initial state.
  - Complexity:  $O(n)$ .
  - It stores too much information and does not find directly a counterexample.

## Automata-Theoretic LTL Model Checking

- $M \models \mathbf{A}\psi$  (CTL\*)
- $\iff M \models \psi$  (LTL)
- $\iff \mathcal{L}(M) \subseteq \mathcal{L}(\psi)$
- $\iff \mathcal{L}(M) \cap \overline{\mathcal{L}(\psi)} = \{\}$
- $\iff \mathcal{L}(A_M) \cap \mathcal{L}(A_{\neg\psi}) = \{\}$
- $\iff \mathcal{L}(A_M \times A_{\neg\psi}) = \{\}$
- $A_M$  is a **Büchi Automaton** equivalent to  $M$  (which represents all and only the executions of  $M$ )
- $A_{\neg\psi}$  is a **Büchi Automaton** which represents all and only the paths that satisfy  $\neg\psi$  (do not satisfy  $\psi$ )
- $\implies A_M \times A_{\neg\psi}$  represents all and only the paths appearing in  $M$  and not in  $\psi$ .

## Automata-Theoretic LTL M.C. (dual version)

- $M \models \mathbf{E}\varphi$
- $\iff M \not\models \mathbf{A}\neg\varphi$
- $\iff \dots$
- $\iff \mathcal{L}(A_M \times A_\varphi) \neq \{\}$ 
  - $A_M$  is a **Büchi Automaton** equivalent to  $M$  (which represents all and only the executions of  $M$ )
  - $A_\varphi$  is a **Büchi Automaton** which represents all and only the paths that satisfy  $\varphi$
- $\implies A_M \times A_\varphi$  represents all and only the paths appearing in both  $A_M$  and  $A_\varphi$ .

## Automata-Theoretic LTL Model Checking

Four steps:

- 1 Compute  $A_M$
- 2 Compute  $A_\varphi$
- 3 Compute the product  $A_M \times A_\varphi$
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$

## Computing an NBA $A_M$ from a Kripke Structure $M$

- Transforming a K.S.  $M = \langle S, S_0, R, L, AP \rangle$  into an NBA  $A_M = \langle Q, \Sigma, \delta, I, F \rangle$  s.t.:
  - States:  $Q := S \cup \{init\}$ ,  $init$  being a new initial state
  - Alphabet:  $\Sigma := 2^{AP}$
  - Initial State:  $I := \{init\}$
  - Accepting States:  $F := Q = S \cup \{init\}$
  - Transitions:

$$\delta : \begin{array}{l} q \xrightarrow{a} q' \text{ iff } (q, q') \in R \text{ and } L(q') = a \\ init \xrightarrow{a} q \text{ iff } q \in S_0 \text{ and } L(q) = a \end{array}$$

- $\mathcal{L}(A_M) = \mathcal{L}(M)$
- $|A_M| = |M| + 1$

# Computing a NBA $A_M$ from a Kripke Structure $M$ : Example

$\implies$  Substantially, add one initial state, move labels from states to incoming edges, set all states as accepting states

## Labels on Kripke Structures and BA's - Remark

Note that the labels of a Büchi Automaton are different from the labels of a Kripke Structure. Also graphically, they are interpreted differently:

- in a Kripke Structure, it means that  $p$  is true and all other propositions are false;
- in a Büchi Automaton, it means that  $p$  is true and all other propositions are uncertain (they can be either true or false).

## Translation problem

### Problem

Given an LTL formula  $\phi$ , find a Büchi Automaton that accepts the same language of  $\phi$ .

- It is a fundamental problem in LTL model checking (in other words, every model checking algorithm that verifies the correctness of an LTL formula translates it in some sort of finite-state machine).
- We will translate LTL in a (equivalent) variant of Büchi Automata called Labeled Generalized Büchi Automata (LGBA).

## Translation from LTL to Büchi Automata: examples

- $\blacklozenge P$

$$\mathcal{L} = \text{true}^* P \text{true}^\omega$$

- $Q U P$

$$\mathcal{L} = Q^* P \text{true}^\omega$$

- $\blacksquare P$

$$\mathcal{L} = P^\omega$$

- $Q U \bullet \bullet P$

$$\mathcal{L} = Q^* \text{true true } P \text{true}^\omega$$

## Translation from LTL to Büchi Automata: examples

- $\blacksquare (P \rightarrow \blacklozenge Q)$

$$\mathcal{L} = (\text{not } P^* P \text{true } Q \text{true})^\omega U (\text{not } P^* P \text{true } Q \text{true})^* \text{not } P^\omega$$

- $\blacksquare \blacklozenge P$

$$\mathcal{L} = (\text{true}^* P)^\omega$$

- $\blacklozenge \blacksquare P$

$$\mathcal{L} = \text{true}^* P^\omega$$

  - Exponential construction of Büchi Automata
  - On-the-fly construction of Büchi Automata
  - Complexity

## Automata-Theoretic LTL Model Checking: complexity

Four steps:

- 1 Compute  $A_M$ :
- 2 Compute  $A_\varphi$ :
- 3 Compute the product  $A_M \times A_\varphi$ :
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$ :

## Automata-Theoretic LTL Model Checking: complexity

Four steps:

- 1 Compute  $A_M$ :  $|A_M| = O(|M|)$
- 2 Compute  $A_\varphi$ :
- 3 Compute the product  $A_M \times A_\varphi$ :
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$ :

## Automata-Theoretic LTL Model Checking: complexity

Four steps:

- 1 Compute  $A_M$ :  $|A_M| = O(|M|)$
- 2 Compute  $A_\varphi$ :  $|A_\varphi| = O(2^{|\varphi|})$
- 3 Compute the product  $A_M \times A_\varphi$ :
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$ :

## Automata-Theoretic LTL Model Checking: complexity

Four steps:

- 1 Compute  $A_M$ :  $|A_M| = O(|M|)$
- 2 Compute  $A_\varphi$ :  $|A_\varphi| = O(2^{|\varphi|})$
- 3 Compute the product  $A_M \times A_\varphi$ :  
 $|A_M \times A_\varphi| = |A_M| \cdot |A_\varphi| = O(|M| \cdot 2^{|\varphi|})$
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$ :

## Automata-Theoretic LTL Model Checking: complexity

Four steps:

- 1 Compute  $A_M$ :  $|A_M| = O(|M|)$
- 2 Compute  $A_\varphi$ :  $|A_\varphi| = O(2^{|\varphi|})$
- 3 Compute the product  $A_M \times A_\varphi$ :  
 $|A_M \times A_\varphi| = |A_M| \cdot |A_\varphi| = O(|M| \cdot 2^{|\varphi|})$
- 4 Check the emptiness of  $\mathcal{L}(A_M \times A_\varphi)$ :  $O(|A_M \times A_\varphi|) = O(|M| \cdot 2^{|\varphi|})$

$\implies$  the complexity of LTL M.C. grows linearly wrt. the size of the model  $M$  and exponentially wrt. the size of the property  $\varphi$

## Final Remarks

- Büchi automata are in general more expressive than LTL!
  - ⇒ Some tools (e.g., Spin, ObjectGEODE) allow specifications to be expressed directly as NBAs
  - ⇒ complementation of NBA important!
- for every LTL formula, there are many possible equivalent NBAs
  - ⇒ lots of research for finding “the best” conversion algorithm
- performing the product and checking emptiness very relevant
  - ⇒ lots of techniques developed (e.g., partial order reduction)
  - ⇒ lots on ongoing research
